

Nomenclatural novelties : Alfredo Vizzini

Hygrophorocybe Vizzini & Contu, gen.nov.

IF550629

Basidiomes agaricoid (stipitate-pileate with lamellate hymenophore). Pileus at first broadly convex then expanding, plane or obtusely umboinate, rarely infundibuliform when old; surface dry, pruinose, sometimes rivulose to cracked, whitish; margin at first inrolled, minutely ribbed and pruinose to velutinous. Lamellae decurrent, subdistant to distant, narrow, often forked or anastomosing, pinkish-cream to yellowish at maturity, easily separable from the pileus context. Stipe central, concolourous to the stipe. Veils absent. Context thick at pileus centre, white. Spore-print whitish to pinkish-cream. Spores large, up to 10×4.5 (-5.0) μm (from 4-spored basidia), ellipsoid to oblong, sometimes sublacrymoid in profile, smooth, thin- to moderately thick-walled, inamyloid, non-dextrinoid, cyanophobic, not released in tetrads. Basidia hygrophoroid, up to $50 \times 6-8 \mu\text{m}$, usually 4-spored, rarely 1- or 2-spored, sterigmata sometimes delimited by secondary septa; sclerobasidia (crassobasidia) occasionally present. Cystidia of any kind absent. Pileipellis a cutis consisting of cylindrical hyphae sometimes with rare and short diverticula. Hymenophoral trama regular, consisting of subparallel, undulate hyphae. Clamp connections present. Hyphal system monomitic. On litter, usually in conifer woods.

Holotype: *Clitocybe nivea* Velen. 1920.

Etymology: Derived from the fusion of the genus names *Hygrophorus* and *Clitocybe* and refer to the basidiomata showing a mix of both hygrophoroid and clitocyboid features
